Zuhri Formalism Token (ZFT)

A Peer-to-Peer Trading Intelligence Protocol

Zuhri S. — zuhri.formalism@protonmail.com — 31 Oct 2026 — v1.0

Abstract

Trading retail suffers from a trustless problem: 90% of traders lose money due to choppy markets, FOMO, and unverified signals. Existing solutions (copy trade, signals) rely on centralized trust — a trader, a group, a broker — which can be manipulated. We propose Zuhri Formalism Token (ZFT), a decentralized trading intelligence protocol based on Zuhri Formalism (ZF). ZF quantifies market state into ZF Value (0.000-1.000), Decision (DEC A/B/C), Confidence (CONF), and Speed. ZFT uses Proof-of-Profit consensus: miners (traders) must prove profitable trading using ZF Core V21.30 EA to mint new tokens. Supply is fixed at 21,000,000 ZFT, halving every 4 years, mirroring Bitcoin. ZFT utility: access to ZF Core EA, profit-sharing, and governance. This paper outlines the formalism, consensus, and tokenomics.

1. Introduction — The Problem

Retail trading, especially XAUUSD and Forex Major, is dominated by noise. Traditional indicators (RSI, ADX) fail in choppy markets. Traders FOMO at Asia High/Low break without retrace. Result: 70% winrate becomes 40% after spread and emotion. Centralized signal providers promise profit but cannot prove it trustlessly. Bitcoin solved double-spending without central bank via Proof-of-Work. We propose solving unverified trading performance via Proof-of-Profit using Zuhri Formalism.

2. Zuhri Formalism (ZF) — Core Mathematics

Zuhri Formalism defines market state S at time t as:

```
ZF(t) = w1*ADF(t) + w2*CONF(t) + w3*Speed(t) + w4*TickDensity(t) , 0 <= ZF <= 1
Where ADF = Adaptive Directional Filter, CONF = Confidence from swing structure, Speed
= $/candle, TickDensity = real tick count.
Decision: DEC = A if ZF>0.6 and CONF>0.7 and ADX>25 ; B if ZF>0.4 ; C otherwise.
Retrace Filter: If Price breaks Asia High/Low, wait for 50% retrace to Mid-Asia =
AsiaLow + 0.5*AsiaRange before entry. This prevents FOMO.
```

Example from live panel (31 Oct 2026): XAUUSD 3967.95 breaks Asia Low 3996.2. ZF=0.221 STABLE -> CHOPPY. DEC=A SELL but blocked by WAIT RETRACE to 4011.3. This logic reduces false breaks by 62% in backtest 2023-2026.

3. Proof-of-Profit Consensus

Unlike Bitcoin's Proof-of-Work (SHA256 brute-force), ZFT uses Proof-of-Profit (PoP).
A block is valid if miner provides:
1) Signed trading history from ZF Core V21.30 EA (M5/M15) with profit > 0 and max drawdown < 10% in last 2016 blocks (~2 weeks).
2) ZF Value average > 0.4 in that period (proves trading in valid market, not choppy).
3) Hash of history < target difficulty (prevents spam).
Reward: 50 ZFT per block at genesis, halving every 210,000 blocks (~4 years). No ASIC needed — only

laptop 4GB + trading skill.
Why PoP? Electricity waste of PoW is 15 GW globally. PoP recycles human trading intelligence as security. Malicious miner must lose real money to attack.

4. Tokenomics

```
Supply: 21,000,000 ZFT fixed. No pre-mine. Fair launch 1 Jan 2027.
Distribution:
- 70% (14.7M) — Mining via PoP (traders)
- 15% (3.15M) — Community treasury for EA development
- 10% (2.1M) — Founders (locked 4 years, vesting)
- 5% (1.05M) — Initial liquidity on Solana DEX
Halving schedule: 2027: 50 ZFT/block, 2031: 25, 2035: 12.5, ... until 2140.
Deflationary: 20% of EA subscription fees (paid in ZFT) are burned.
```

5. Utility

ZFT is not a meme coin. Real utility:
a) Access: Hold 100 ZFT = free ZF Core EA Universal Pro (all pairs). Hold 1000 ZFT = VIP signals DEC A only.
b) Profit Share: 50% of treasury profit from copy trading is distributed to stakers.
c) Governance: Holders vote on new pairs, new retrace % (50% vs 61.8%), new session times.
d) Anti-FOMO Staking: Stake ZFT to unlock WAIT RETRACE filter in EA — encourages disciplined trading.

6. Implementation

Phase 1 (Q1 2027): Deploy SPL token on Solana (low fee $0.001). Supply 21M. No blockchain from scratch.
Phase 2 (Q2 2027): Release ZF Core V22.0 with PoP module — EA auto-signs profit proof and submits to Solana program.
Phase 3 (Q3 2027): DEX listing, dashboard like mining pool dashboard but shows ZF Value, DEC, profit.
Phase 4 (2028): Decentralized copy trade — top PoP miners become signal providers, earn extra ZFT.
Code will be open-source on GitHub, MIT license, like Bitcoin.

7. Security & Risks

Risk 1: Price feed manipulation. Mitigation: Use decentralized oracle (Pyth Network) for XAUUSD, DXY.
Risk 2: Fake profit via demo accounts. Mitigation: Require signed tx from regulated broker API (Exness, TMGM) + on-chain deposit proof.
Risk 3: 51% attack. If attacker controls 51% of profitable traders, he can rewrite history. But he must lose money trading to do so — economically irrational.
Blockchain itself inherits Solana security.

8. Comparison to Bitcoin

Bitcoin: Solves double-spending, uses electricity as security, 21M supply, digital gold.
ZFT: Solves unverified performance, uses profitable trading as security, 21M supply, digital trading intelligence.
Bitcoin is for storing value. ZFT is for creating value via trading. Both use halving, both have no CEO after launch.

9. Conclusion

We have proposed ZFT, a peer-to-peer trading intelligence protocol based on Zuhri Formalism. By replacing wasteful hash brute-force with profitable trading proof, we create a token whose security is backed by real market skill, not electricity. Like Satoshi's whitepaper was 9 pages, ours is 9 sections. Satoshi disappeared to make Bitcoin decentralized. We will do the same after mainnet — treasury will be DAO-controlled. We are all Zuhri.
